Algebraic Topology Notes

Thomas Chaplin

1 Simplicial Homology

The standard k-simplex is

$$\Delta^k := \left\{ (x_0, \dots x_k) \in \mathbb{R}^{k+1} \mid \sum_{i=0}^k x_i = 1, \quad x_i \ge 0 \right\}$$

Given $v_0, \ldots, v_k \in \mathbb{R}^N$ we define the simplex by

$$[v_0, \dots v_k] := \left\{ \sum_{i=0}^k x_i v_i \mid \sum_{i=0}^k x_i = 1, \quad x_i \ge 0 \right\}$$

so than $\Delta^k = [e_0, \dots, e_k]$.

This yields an obvious map $\sigma: \Delta^k \to [v_0, \dots v_k]$

$$\sigma(x_0, \dots x_k) = \sum_{x_i v_i}$$

We will often, confusingly, denote this map $[v_0, \dots v_k]$.

We say v_0, \ldots, v_k are in general position if they do not lie on any (k-1)-dimensional affine subspace.

Proposition 1.1. v_0, \ldots, v_k are in general position $\iff \sigma$ is a homeomorphism.

We can then define the map $i_j: \Delta^{k-1} \to \Delta^k$ to be the map $[e_0, \dots, e_{j-1}, e_{j+1}, \dots, e_k]$. This map then parametrises the face opposite the vector e_j . The union of the k-1 dimensional faces of $[v_0, \dots, v_k]$ is its boundary and its interior is $[v_0, \dots, v_k]$.

A Δ -complex structure on a space X is a collection of maps $\sigma_{\alpha}: \Delta^k \to X$ for varying k such that

- 1. $\sigma_{\alpha}: (\Delta^k)^{\circ} \to X$ is injective and each point of X lies in the image of exactly one interior.
- 2. If $\sigma_{\alpha}: \Delta^k \to X$ is in the collection then $\sigma_{\alpha} \circ i_j: \Delta^{k-1} \to X$ is also for $j = 0, \dots, k$.
- 3. $U \subseteq X$ is open $\iff \sigma_{\alpha}^{-1}(U)$ is open in Δ^k for all α .

We then define the spaces of formal sum of simplicies

$$\Delta_n(X) := \left\{ \sum m_{\alpha} \sigma_{\alpha}^n \mid \text{ formal sums with integer coeffs and } \sigma_{\alpha}^n \text{ are n-simplicies} \right\}$$

and then we can define the boundary operator $\partial_n: \Delta_n(X) \to \Delta_{n-1}(X)$ by

$$\partial_n(\sigma_\alpha^n) = \sum_{j=0}^n (-1)^j (\sigma_\alpha^n \circ i_j) = \sum_{j=0}^n (-1)^j \sigma_\alpha^n \big|_{[e_0, \dots, \hat{e_j}, \dots, e_n]}$$

where $\hat{e_j}$ means that we omit the j'th vertex.

Then the loops are elements in $\ker \partial_n$ but we don't care about loops that are themselves the boundaries of higher order simplicies since these loops can be contracted through the higher-order simplicies.

We define the n'th homology of the Δ -complex structure to be

$$H_n^{\Delta} := \frac{\ker(\partial_n)}{\operatorname{im}(\partial_{n+1})}$$

2 Singular Homology

Simplicial homology is very computable but has a number of problems that prevent from having far reaching consequences to topology.

- 1. $\Delta_n(X)$ depends on the choice of Δ complex structure so perhaps H_n^{Δ} does too?
- 2. We would like functoriality. If X, Y have Δ -complex structures and $f: X \to Y$ is continuous, how do we then define a homomorphism $H_n^{\Delta}(X) \to H_n^{\Delta}(Y)$?

These problems can be remedied by studying the more complicated and seemingly incomputable singular homology. Instead of considering only simplicies $\Delta^n \to X$ in the Δ complex structure we allow all continuous maps $\Delta^n \to X$ which we call singular *n*-simplicies.

 $C_n(X) := \{ \text{finite formal sums of singular n-simplicies} \} = \text{Free AbGr on singular n-simplicies} \}$

We can then define $\partial_n(X) \to C_{n-1}(X)$ in exactly the same way as before and then define singular homology

$$H_n(x) := \frac{\ker \partial_n}{\operatorname{im} \partial_{n+1}}$$

Note:

$$\partial_n \circ \partial_{n+1} = 0$$

2.1 Functoriality

If we have a continuous map $f: X \to Y$ then we can define

$$f_{\#}: C_n(X) \to C_n(Y), \quad \sigma \mapsto f \circ \sigma$$

on the *n*-simplicies and then extend it to all of $C_n(X)$ linearly so that

$$f_{\#}\left(\sum_{\alpha}m_{\alpha}\sigma_{\alpha}\right) = \sum_{\alpha}m_{\alpha}\left(f\circ\sigma_{\alpha}\right)$$

Lemma 2.1.

$$\partial(f_{\#}\sigma) = f_{\#}(\partial\sigma)$$

Proof.

$$\partial(f_{\#}\sigma) = \partial((f \circ \sigma)) = \sum_{j=0}^{n} (-1)^{j} (f \circ \sigma) \circ i_{j}$$

$$f_{\#}(\partial\sigma) = f_{\#}\left(\sum_{j=0}^{n} (-1)^{j} (\sigma \circ i_{j})\right) = \sum_{j=0}^{n} (-1)^{j} f \circ (\sigma \circ i_{j})$$

We can also extend this result to any formal sum of n-simplicies in $C_n(X)$. Hence $f_\#$ induces a morphism of chain complexes. The morphism arises due to this commutativity and it is of chain complexes because we have $\partial^2 = 0$.

Corollary 2.2. From this diagram we can see that

- 1. $f_{\#}(\underbrace{\ker \partial_n}) \subseteq \underbrace{\ker \partial_n}_{\subseteq C_n(Y)}$.
- 2. $f_{\#}(\operatorname{im} \partial_n) \subseteq \operatorname{im} \partial_n$.

and hence $f_{\#}$ induces a homomorphism $f_*: H_n(X) \to H_n(Y)$ because if you differ be an element of $\operatorname{im} \partial_{n+1}$ in $H_n(x)$ then you will still differ by an image element in $H_n(Y)$.

Elements of ker ∂ are called cycles and elements of im ∂ are called boundaries.

$$B_n(X) := \operatorname{im} \partial_{n+1} \subseteq C_n(X)$$

 $Z_n(X) := \ker \partial_n \subseteq C_n(X)$

so the $H_n(X) = \frac{Z_n}{B_n}$ and the induced map f_* is given be

$$f_*(c + B_n(X)) := f_\#(c) + B_n(Y)$$

Theorem 2.3.

$$(f \circ g)_* = f_* \circ f_*$$
 and $(id_X)_* = id_{H_n(X)} \ \forall n$

and hence singular homology is a functor.

This implies the important result that

$$X \underset{\text{homeo}}{\cong} Y \implies H_n(X) \underset{\text{iso}}{\cong} H_n(Y) \ \forall n$$

2.2 Basic computation of singular homology

Here are some important results.

Theorem 2.4.

$$H_n(\{pt\}) = \begin{cases} \mathbb{Z} & \text{if } n = 0\\ 0 & \text{if } n > 0 \end{cases}$$

Note: Δ^n is path connected so every continuous map $\sigma:\Delta^n\to X$ falls in one path component. Hence

$$C_n(X) = \bigoplus_{\text{path components } X_i} C_n(X_i)$$

Moreover $\partial_n(C_n(X_i) \subseteq C_{n-1}(X_i)$ so the chain complexes of the path components are independent of one another and hence we have

$$H_n(X) = \bigoplus_{X_i} H_n(X_i)$$

Theorem 2.5. X path connected $\iff H_0(X) \cong X$.

2.3 Reduced Homology

It often makes sense to add one extra space to the chain complex under to state results more succinctly, so we modify the chain complex as so

$$\ldots \longrightarrow C_n(X) \longrightarrow \ldots \longrightarrow C_1(x) \xrightarrow{\partial_1} C_0(X) \xrightarrow{\epsilon} \mathbb{Z} \longrightarrow 0$$

where we introduce anew map $\epsilon: C_0(X) \to \mathbb{Z}$ which just sums coefficients:

$$\epsilon \left(\sum m_{\alpha}[p_{\alpha}] \right) \mapsto \sum m_{\alpha}$$

then we define the reduced homologies to be the same $\widetilde{H}_n(X) = H_n(X)$ for n > 0 but then

$$\widetilde{H}_0(X) := \frac{\ker \epsilon}{\operatorname{im} \partial_1} \neq H_0(X)$$

We can realise the relation of H_0 and \widetilde{H}_0 by the following commutative diagram:

$$\ker \epsilon \xrightarrow{i} C_0(X)$$

$$\downarrow_{\overline{\operatorname{im}}\partial_1} \qquad \downarrow_{\overline{\operatorname{im}}\partial_1}$$

$$\widetilde{H}_0(X) \xrightarrow{i} H_0(X)$$

This diagram commutes and hence the map ϵ passes to the quotient to define

$$\bar{\epsilon}: H_0(X) \to \mathbb{Z}$$

and then $\widetilde{H}_0(X) = \ker \overline{\epsilon}$.

3 Exact sequences

A sequence of abelian groups A_n and homomorphisms ϕ_n is a complex if $\operatorname{im} \phi_{n+1} \subseteq \ker \phi_n$ for all n.

$$\dots \xrightarrow{\phi_{n+2}} A_{n+1} \xrightarrow{\phi_{n+1}} A_n \xrightarrow{\phi_n} A_{n-1} \xrightarrow{\phi_{n-1}} \dots$$

The complex is exact if im $\phi_{n+1} = \ker \phi_n$ for all n.

Note: Whenever we have such a chain complex we can assign the n-th homology to be

$$\frac{\ker \phi_n}{\operatorname{im} \phi_{n+1}}$$

So assuming that X is non-empty we get the following exact sequence

$$0 \longrightarrow \widetilde{H}_0(X) \hookrightarrow H_0(X) \stackrel{\overline{\epsilon}}{\longrightarrow} \mathbb{Z} \longrightarrow 0$$

Given $A \subseteq X$ both topological spaces then we say (X, A) is a pair. Further, we say they are a good pair if A is a deformation retract of some neighbourhood in X.

Theorem 3.1. If (X,A) is a good pair then there exists a long exact sequence

$$0 \longrightarrow \widetilde{H}_n(A) \xrightarrow{i_*} \widetilde{H}_n(X) \xrightarrow{q_*} \widetilde{H}_n(\frac{X}{A})$$

$$\widetilde{H}_{n-1}(A) \xrightarrow{i_*} \widetilde{H}_{n-1}(X) \xrightarrow{q_*} \widetilde{H}_{n-1}(\frac{X}{A})$$

$$\widetilde{H}_0(A) \xrightarrow{i_*} \widetilde{H}_0(X) \xrightarrow{q_*} \widetilde{H}_0(\frac{X}{A}) \longrightarrow 0$$

We can then use this long exact sequence with the pair (S^{n-1}, D^n) .

$$0 \longrightarrow \widetilde{H}_{n}(S^{n-1}) \xrightarrow{i_{*}} \widetilde{H}_{n}(D^{n}) \xrightarrow{0} \xrightarrow{q_{*}} \widetilde{H}_{n}\left(\frac{D^{n}}{S^{n-1}}\right)$$

$$\widetilde{H}_{n-1}(S^{n-1}) \xrightarrow{i_{*}} \widetilde{H}_{n-1}(D^{n}) \xrightarrow{0} \xrightarrow{q_{*}} \widetilde{H}_{n-1}\left(\frac{D^{n}}{S^{n-1}}\right)$$

$$\widetilde{H}_{0}(S^{n-1}) \xrightarrow{i_{*}} \widetilde{H}_{0}(D^{n}) \xrightarrow{0} \xrightarrow{q_{*}} \widetilde{H}_{0}\left(\frac{D^{n}}{S^{n-1}}\right) \longrightarrow 0$$

Thanks to the exactness of this sequence we see that

$$\widetilde{H}_n(S^{n-1}) \cong \widetilde{H}_n\left(\frac{D^n}{S^{n-1}}\right) \cong \widetilde{H}_n(S^n)$$

and hence

$$\widetilde{H}_k(S^n) = \begin{cases} 0 & \text{if } k < n \\ \mathbb{Z} & \text{if } k = n \\ 0 & \text{if } k > n \end{cases}$$

We will often find short exact sequences with are sequences that look like

$$0 \longrightarrow A \hookrightarrow B \longrightarrow C \longrightarrow 0$$

in which case the first isomorphism theorem tells us that $C \cong \frac{B}{A}$.

4 Relative homologies

Given a pair (X, A) we can define the relative chain group

$$C_n(X,A) := \frac{C_n(X)}{C_n(A)}$$

i.e. we consider two continuous maps into X to be the same if the agree on $X \setminus A$. Now our maps ∂_n pass to the quotient by

$$\overline{\partial}_n(c + C_n(A)) := \partial_n(c) + C_{n-1}(A)$$

which is well defined because the boundary of a chain in A is still a chain in A. We still get $\overline{\partial}_n \circ \overline{\partial}_{n+1} = 0$ and hence we can define the relative homology groups

$$H_n(X,A) := \frac{\ker \overline{\partial}_n}{\operatorname{im} \overline{\partial}_{n+1}}$$

Notice that given a pair of spaces (X, A), we get a short exact sequence of chain complexes

$$0 \longrightarrow C_n(A) \xrightarrow{i_\#} C_n(X) \xrightarrow{j_\#} C_n(X,A) \longrightarrow 0$$

Theorem 4.1. Given any short exact sequence of chain complexes

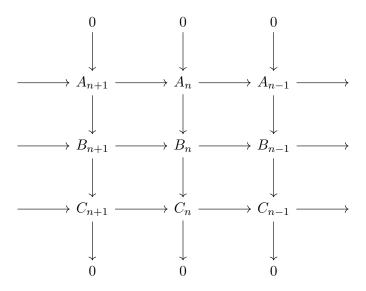

$$0 \longrightarrow A_{\bullet} \stackrel{i}{\longrightarrow} B_{\bullet} \stackrel{j}{\longrightarrow} C_{\bullet} \longrightarrow 0$$

we get a long exact sequence of homology:

where the connecting homomorphism is defined by diagram chasing.

Proof. We construct the connecting homomorphism $\delta: H_n(C_{\bullet}) \to H_{n-1}(A_{\bullet})$ as per the following diagram. Remember that

- Columns are exact sequences.
- Rows are complexes.

We need to prove this is well defined, that is:

- 1. Independent of our choice of representative $c_n \in [c_n]$
- 2. Independent of our choice of b_n such that $j(b_n) = c_n$.

Then we need to prove exactness at each point in the sequence.

This gives us a long exact sequence of relative homology but unfortunately we cannot yet use it to prove anything about $\widetilde{H}_n\left(\frac{X}{A}\right)$ because the sequence only includes terms like $\widetilde{H}_n(X,A)$. We would like to show that for a good pair

$$\widetilde{H}_n\left(\frac{X}{A}\right) \cong \widetilde{H}_n(X,A)$$

First homotopy invariance of homology and a relationship between π_1 and H_1 .

5 Homotopy Invariance of Homology

Theorem 5.1. Homotopy maps $f, g: X \to Y$ induce the same homomorphism of homology, i.e. $f_* = g_*$.

Proof. This is the proof where we construct the prism operator. It is very long and complicated but the main ideas should be remembered. \Box

Corollary 5.2. If $h: X \to Y$ is a homotopy equivalence then $h_*: H_n(X) \to H_n(Y)$ is an isomorphism for every $n \in \mathbb{N}$.

Proof. This is now a simple application of functoriality.

Note: In particular, a contractible space has the same homology as a point.

Suppose p,q are morphisms of chain complexes $A_{\bullet} \to B_{\bullet}$.

We say they are chain homotopic if there is a $P: A_n \to B_{n+1}$ for each n such that

$$p - q = \partial P + P \partial$$

6 Relation between π_1 and H_1

For this section assume that X is path connected and $x_0 \in X$ Consider the map which realises a loop in X based at x_0 as a cycle in $Z_1(X)$. We claim that his passes to the quotient to define

$$h: \pi_1(X, x_0) \to Z_1(X)$$

Moreover, we claim

- (i) h is a homomorphism.
- (ii) h is surjective.
- (iii) $\ker h = [\pi_1(X, x_0), \pi_1(X, x_0)]$ is the commutator subgroup.

Hence by the first isomorphism theorem $H_1(X)$ can be seen as the abelianisation of $\pi_1(X, x_0)$

$$H_1(X) \cong \frac{\pi_1(X, x_0)}{[\pi_1(X, x_0), \pi_1(X, x_0)]} =: \pi_1(X, x_0)_{ab}$$

Proof. Again this is very long but an understanding of the main argument would be useful. Consult Hatcher for more details. \Box

7 Homology: Civil War

Theorem 7.1. The inclusion of $\Delta_{\bullet}(X) \to C_{\bullet}(X)$ induces an isomorphism

$$H_n^{\Delta}(X) \to H_n(X)$$

when X is a Δ -complex.

This is quite a long road so we start with the following very important technical result. The idea is that if we remove chains deep inside A then we do not effect the relative homology because they have already been quotiented out.

Theorem 7.2 (Excision). Given spaces $Z \subseteq A \subseteq X$ such that $\overline{Z} \subseteq A^{\circ}$. Then the inclusion $(X \setminus Z, A \setminus Z) \to (X, A)$ induces an isomorphism of relative homology

$$H_n(X \setminus Z, A \setminus Z) \to H_n(X, A) \quad \forall n$$

Version 2: If $A, B \subseteq X$ such that $A^{\circ} \cup B^{\circ} \subseteq X$ then the inclusion $(B, A \cap B) \to (X, A)$ induces an isomorphism $H_n(B, A \cap B) \to H_n(X, A)$ for every n.

We prove venison 2. Notice that $\{A, B\}$ forms a cover of X. Suppose we have a cover $\mathcal{U} = \{U_{\alpha}\}_{\alpha}$ then we can define

$$C_n^{\mathcal{U}}(X) := \{n\text{-chains in } X \text{ where each simplex lies in some } \alpha\}$$

and we clearly get an inclusion $i: C^{\mathcal{U}}_{\bullet}(X) \to C_{\bullet}(X)$.

Proposition 7.3. As defined above i is a chain homotopy equivalent. That is there is some $S: C_{\bullet}(X) \to C_{\bullet}(X)^{\mathcal{U}}$ such that

- $i \circ S : C_{\bullet}(X) \to C_{\bullet}(X)$ is chain homotopic to the identity.
- $S \circ i : C^{\mathcal{U}}_{\bullet}(X) \to C^{\mathcal{U}}_{\bullet}(X)$ is chain homotopic to the identity.

Proof. This was done by barycentric subdivision. By iterated barycentric subdivision, given any singular n-simplex $\sigma: \Delta^n \to X$ we subdivide Δ^n to define a chain $S(\sigma)$ which lies in $C_n^{\mathcal{U}}(X)$. This works because $\partial(subdivision) = subsdivision(\partial)$.

Out first application of excision gives us a relationship between relative homology and homology of quotient spaces.

Proposition 7.4. For a **good pair** (X,A), the quotient map $q:(X,A)\to \left(\frac{X}{A},\frac{A}{A}\right)$ induces an isomorphism

$$H_n(X,A) \to H_n\left(\frac{X}{A}, \frac{A}{A}\right) \cong \widetilde{H}_n\left(\frac{X}{A}\right)$$

8 Useful Results

Lemma 8.1. A continuous bijection from a compact space to a Hausdorff space is a homeomorphism.

Proposition 8.2. Given an equivalent relation \sim and a continuous map $f: X \to Y$ that respects the relation, $\frac{f}{\sim} : \frac{X}{\sim} \to Y$ is also continuous.
